Harmonic Analysis and Big Data: Data Dependent Representations

Wojciech Czaja

Institute for Mathematics and Its Applications 2015 PI Summer Graduate Program College Park, August 5–7, 2015

- We have introduced several examples of data dependent representation methods, such as PCA or Laplacian Eigenmaps.
- These methods are well suited for the analysis of complex, noisy, high-dimensional data.
- As a drawback, we are going to encounter increased computational requirements in comparison to fast a priori methods, such as FFT or DWT.
- Also, the nonlinear dimensionality reduction methods such as LE or SE are typically non-invertible.
- We shall show today how to resolve some of these limitations.

Today we shall cover several important topics:

- The computational bottleneck of data dependent methods;
- Approximate preimage for kernel methods;
- Diffusion wavelets;
- Frames for real data applications.
- Data recovery based on LE.

Output normalized DR methods provide us with good approximate models for complex heterogeneous data structures. However, the computation of those approximations comes at a price.

- If D is the ambient dimension, and N is the number of points, time complexity of constructing an adjacency graph is O(DN²).
- What can we do about D?
- What can we do about the exponent 2?
- What can we do about N?
- What can we do about the computational complexity of eigendecomposition?

- Data Compression via Incoherent Random Projections
- Past Approximate k Nearest Neighbors algorithms
- Quantization Landmarking
- 8 Randomized low-rank SVD decompositions

1. Setting for data compression

- Dataset {*x*₁, *x*₂, ..., *x_N*} in ℝ^D, sampled from a compact *K*-dimensional Riemannian manifold
- Assume $||x_i x_j|| \le A$ for all i, j and some A > 0
- Let 0 < λ₁ ≤ λ₂ ≤ ··· ≤ λ_K be the first *K* nonzero eigenvalues computed by LE, assumed simple, with *r* = min_{i,j} |λ_i − λ_j|, and let *f_j* be a normalized eigenvector corresponding to λ_j
- Use a random orthogonal projector Φ to map the points to ℝ^M.
 Let f̂_j be the *j*th eigenvector computed by LE for the projected data set

Theorem (with A. Halevy)

Fix $0 < \alpha < 1$ and $0 < \rho < 1$. If

$$M \geq rac{4-2\ln(1/
ho)}{\epsilon^2/200+\epsilon^3/3000} K \ln(CKD/\epsilon), \ \textit{where} \ \epsilon = rac{rlpha}{4AN(N-1)},$$

then, with probability at least $1 - \rho$,

$$\|f_j - \hat{f}_j\| < \alpha.$$

The constant C depends on properties of the manifold. Precisely, $C = \frac{1900RV}{\tau^{1/3}}$, where R, V and $1/\tau$ are the geodesic covering regularity, volume, and condition number, respectively.

Similar results for other output normalized DR methods, e.g., for Schroedinger Eigenmaps.

2. Fast Approximate k Nearest Neighbors

- There are many approximate nearest neighbor algorithms, e.g., Locality-sensitive Hashing (P. Indyk), Best Bin First (D. Lowe), or Clustered Point Sets Search (D. Mount). We present the Divide and Conquer method of Chen, Fang, and Saad
- Divide the set of points into two overlapping subsets using spectral bisection based on the Lanczos algorithm
- Once the size of a subset is less than a threshold *r*, compute using brute-force.
- If a point belongs to more than one subset, its nearest neighbors are selected from the neighbors in each of the subsets.

J. Chen, H.Fang and Y. Saad, Y. Fast Approximate kNN Graph Construction for High Dimensional Data via Becursive Lanczos Bisectio

2. Numerical Experiments: Synthetic Data

Figure : Mapping a one-dimensional helix embedded in \mathbb{R}^3 . In the above example the exponent used is approx. 1.16 (depends on the size of overlap).

4. Approximate SVD

- Rokhlin, Szlam and Tygert introduced a randomized, approximate SVD algorithm (ASVD) that works well when matrix is low rank.
- ASVD algorithm constructs an approximate SVD $U\Sigma V^T$ of a real $m \times n$ matrix A that satisfies

$$||\boldsymbol{A} - \boldsymbol{U}\boldsymbol{\Sigma}\boldsymbol{V}^{\mathsf{T}}|| \leq \boldsymbol{C}\boldsymbol{m}^{1/(4i+2)}\sigma_{k+1}$$

with high probability.

• Since the normalized graph Laplacian is symmetric, we can use the ASVD algorithm to obtain the *r* largest eigenvalues. However, for the purposes of Laplacian Eigenmaps (LE), we need the smallest eigenvalues. This can be accomplished in the following manner. Let *A* be the normalized graph Laplacian. Use ASVD with r = 1 to compute the largest eigenvalue, σ_1 . Next, use ASVD again to find the largest *r*' eigenvalues of $2\sigma_1 I - A$. The smallest *r*' eigenvalues of *A* are given by subtracting the results of the previous step from $2\sigma_1$.

V. Rokhlin, A. Szlam, and M. Tygert, A randomized algorithm for principal component analysis, SIAM JMAA 2009.

4. Robust Principle Component Analysis

- Consider PCA of data, with a fraction of the entries grossly corrupted due to, e.g., sensor malfunction on some measurements or random pixels occluded by irrelevant data.
- E. Candès (Stanford) introduced a version of PCA that eliminates such gross corruption via compressive sensing.
- Algorithm relies on using Singular Value Decomposition (SVD) which is computationally too expensive.
- It can be combined with V. Rokhlin's (Yale) randomized, approximate SVD algorithm that works well when matrix is low rank.

Speed up of Robust PCA (with A. Cloninger and G. Warnell)

Under certain assumptions on corrupted entries, Rokhlin's randomized SVD algorithm is used to speed up Candès PCA by several orders of magnitude without loss of precision.

or Harmonic Analysis and Application

Preimage Problem

- How to map data back from feature space to input space?
- The pre-image of $\psi \in \mathbb{R}^m$ is a point $x \in \mathbb{R}^d$ such that $\phi(x) = \psi$. Because x may not necessarily exist, this problem is ill-defined. Thus, instead, we look for $x \in \mathbb{R}^d$ such that $\phi(x)$ is "as close as possible" to ψ .
- Optimality criteria for "closeness" include, e.g.,

$$x = \arg\min_{x \in \mathbb{R}^d} \|\phi(x) - \psi\|_2,$$
 (Distance)

or

$$x = \arg \max_{x \in \mathbb{R}^d} \left\langle \frac{\phi(x)}{\|\phi(x)\|}, \frac{\psi}{\|psi\|} \right\rangle.$$
 (Collinearity)

Preimage problem introduced by Mika, Schoelkopf, and Kwok.

Nystroem Extension for Kernel Methods

Given $x \neq x_1, ..., x_N$, the Nystroem extension is an approximation of $\phi(x)$:

$$\widehat{\phi}(\mathbf{x}) = \sum_{i=1}^{N} K_{\mathbf{x},i} \phi(\mathbf{x}_i),$$

where $K_{x,i}$ is a normalized extension of the original kernel:

$$\mathcal{K}_{x,i} = \frac{k(x,x_i)}{\sqrt{\sum\limits_{j=1}^{N} k(x,x_j) \sum\limits_{j=1}^{N} k(x_i,x_j)}}$$

Letting $K_x := [K_{x,i}]_{i=1,...,N}$, we have $\widehat{\phi}(x) = V^* K_x$, for $V = [\phi_1, ..., \phi_m]$. Also, $\|K_x\|_0 = \#\mathcal{N}(x)$ for a nearest neighbor Gaussian kernel.

Wojciech Czaja Harmonic Analysis and Big Data

Sapiro et al. proposed to modify the pre-image problem by using the Nystroem extension. Let $\mathcal{E} \in \mathbb{R}^{m \times N}$ be the Nystroem extension for a general dimension reduction scheme. Create a new objective function by solving:

 $\arg\min_{\boldsymbol{x}\in\mathbb{R}^{D}}\|\mathcal{E}\boldsymbol{K}_{\boldsymbol{x}}-\boldsymbol{\psi}\|_{2}.$

They note that, due to normalization and since ψ is constant, minimizing $\|\mathcal{E}K_x - \psi\|_2$ is equivalent to maximizing the collinearity:

$$\|\boldsymbol{a}-\boldsymbol{b}\|_2^2 = 1 + \langle \boldsymbol{b}, \boldsymbol{b} \rangle - 2 \langle \boldsymbol{a}, \boldsymbol{b} \rangle.$$

However, they also point out that for a generic approximation of a pre-image, one needs to assume that ψ is normalized, as well.

Preimage Problem with Nystroem Extension

Since our objective is now in the form of a linear least squares problem, the optimal K_x can be obtained by, e.g., calculating the Penrose-Moore pseudo-inverse:

$$\widehat{K}_{\mathbf{X}} = \mathcal{E}^{\dagger} \psi.$$

The map \mathcal{E} in our construction is unitary, so we can define the pseudo inverse as, e.g., the left inverse:

$$\mathcal{E}^{\dagger} = (\mathcal{E}^* \mathcal{E})^{-1} \mathcal{E}^*.$$

In the special case of kernel PCA, $K_{x,i} = e^{-\frac{||x-x_i||_2^2}{2\sigma^2}}$. This yields

$$\|\boldsymbol{x}-\boldsymbol{x}_i\|_2^2 = -2\sigma^2\log(\widehat{K}_{\boldsymbol{x},i}).$$

Finding *x* now reduces to a localization problem that is solved using MDS and the distances between *x* and $\mathcal{N}(x)$.

Preimage Problem for LE

- With A. Cloninger and T. Doster (2014).
- Laplacian Eigenmaps does not have a simple, closed form solution that relates K_{x,i} to ||x − x_i||₂, as each K_{x,i} is a function of ||x − x_i||₂ for all x_i ∈ N(x).
- Utilize the sparsity of LE construction, ||K_x||₀ = c ≪ n, to solve for ||x x_i||₂².
- Our approach:
 - Use pseudo-inverse or L^1 regularization to obtain estimates for K_x .
 - Modify the *K_x* term to correct for noise.
 - Use Newton's method or a constrained optimization to solve the resulting system of equations.
 - This solution leads to a localization problem.
 - Solve the localization problem using MDS.

Diffusion maps and diffusion wavelets

 Coifman and Lafon introduced the diffusion distance - a new and efficient metric measuring distances in graphs and point clouds:

$$D_t^2(x,y) = \sum_z \frac{(p(z,t|x) - p(z,t|y))^2}{\phi_0(z)},$$

where each p(z, t|x) is the probability of transition in time *t* from *z* to *x*, and $\phi_0(z)$ is the stationary eigenvector of the probability transition matrix.

R. R. Coifman and S. Lafon, Diffusion maps, Applied and computational harmonic analysis 21 (2006) no. 1, pp. 5–30.

 Coifman and Maggioni used the diffusion distances to construct a new notion of wavelet representations of graphs, diffusion wavelets.

R. R. Coifman and M. Maggioni, "Diffusion wavelets", ACHA , 2006, Vol. 21(1), 53-94.

Diffusion maps and diffusion wavelets

Singer and Wu generalized this concept to vector diffusion maps (VDM).

A. Singer and H. Wu, Vector diffusion maps and the connection Laplacian, Communications on Pure and Applied Mathematics

vol., 65 (2012) no. 8, pp. 1067-1144.

 Bremer, Coifman, Maggioni, and Szlam showed how to construct diffusion wavelet packets, generalizing the classical construction of wavelet packets of Coifman and Wickerhauser.

J. C. Bremer, R. R. Coifman, M. Maggioni, and A. D. Szlam, Diffusion wavelet packets, Applied and Computational Harmonic

Analysis 21 (2006) no. 1, pp. 95-112.

Given is $\{\delta_n\}_{n=1}^N$, the standard orthonormal basis for $V_0 = \mathbb{R}^N$.

$$V_{0} = \operatorname{span} \left\{ \delta_{n} : n = 1, \dots, N \right\}$$

$$\kappa \mid \text{dilation}$$

$$V_{1} = \operatorname{span} \left\{ K(\delta_{n}) : n = 1, \dots, N \right\}$$

 $\{\Phi_n = K(\delta_n)\}_{n=1}^N$ is a frame for $V_1 = \mathbb{K}$.

Wojciech Czaja Harmonic Analysis and Big Data

We want to compute the eigenbasis $\{e_n\}_{n=1}^r$ for K. Recall that

 $V_1 = \mathbb{K} = \operatorname{span} \{ K(\delta_n) : n = 1, \dots, N \}$ and $r = \dim V_1$.

Hence, $\{e_n\}_{n=1}^r$ is an orthonormal basis for *K*.

Diffusion wavelets solution: Use a modified Gramm- Schmidt orthogonalization algorithm on the frame $\{\Phi_n = K(\delta_n)\}_{n=1}^N$ to obtain an orthonormal basis $\{\Psi_n\}_{n=1}^r$ for \mathbb{K} .

- Coifman and Hirn (2013) proposed to use diffusion maps and their embeddings for change detection in hyperspectral imagery over time.
- Diffusion geometry principles via tree structures with evolving graphs were proposed by Lee and Maggioni (2012).
- Evolving Riemannian manifold with changing diffusion processes were studied by H. Abdallah (2010).
- Shape analysis via heat kernels was proposed by F. Mémoli (2011).

- Another solution: Use the frame minimization algorithm on \mathbb{K} to obtain a FUNTF $\{\Psi_n\}_{n=1}^r$. Since $r = \dim \mathbb{K}, \{\Psi_n\}_{n=1}^r$ is an orthonormal basis for \mathbb{K} .
- Additional advantage: A FUNTF generalizes the concept of an orthonormal basis. We can obtain FUNTFs with s elements for any s > r. The truly redundant FUNTFs can be optimized for sparsity.

- Different classes of interest may not be orthogonal to each other; however, they may be captured by different frame elements. It is plausible that classes may correspond to elements in a frame but not elements in a basis.
- A *frame* generalizes the concept of an orthonormal basis. Frame elements are non-orthogonal.
- Frames provide over-complete data decompositions, often useful for numerical stability and noise reduction.

HYDICE Copperas Cove data set

- HYDICE Copperas Cove, TX, HSI dataset with 23 different classes.
- If the 23 classes were to correspond roughly to orthogonal subspaces, then one cannot achieve effective dimension reduction less than dimension d = 23.
- However, we could have a frame with 23 elements in a space of reduced dimension d < 23.

Figure : HYDICE Copperas Cove, TX - http://www.tec.army.mil/Hypercuber Application

Spectral signatures of selected classes

Figure : Spectral signatures of Walmart, pasture, and trees are **not** orthogonal to each other.

Wojciech Czaja Harmonic Analysis and Big Data

Comparison of spectral signatures

We focus on Walmart, pasture, and trees.

Angles between the mean signature of each class:

- Walmart and pasture: 36 degrees.
- Walmart and trees: 42 degrees.
- Pasture and trees: 14 degrees.

Maximum angles between classes:

- Walmart and pasture: 40 degrees.
- Walmart and trees: 49 degrees.
- Pasture and trees: 28 degrees.

Frame optimization problems

Define the $W(\ell^1, \ell^\infty)$ Wiener amalgam penalty term

$$p_k = \sum_{m=1}^N |\langle y_m, \Psi_k \rangle|, \text{ for all } k = 1, \dots, s.$$

Our frame-theoretic method has two steps:

Step 1: Choose q < s and find a pseudo-FUNTF $\Psi = {\{\Psi_k\}}_{k=1}^s$ by solving the following minimization problem:

$$\Psi = \arg\min_{\widetilde{\Psi}} TFP(\widetilde{\Psi}) + \frac{s^2}{d} \sum_{k=q+1}^{s} p_k.$$
(1)

 (1) is solved using a gradient descent method. The method is initialized with a d × s matrix with entries that are uniformly distributed on [0, 1]. **Step 2:** Solve for the minimum ℓ^1 norm coefficients of the frame Ψ :

$$\forall m = 1, \dots, N, \ \widehat{a}_m = \arg\min_{\widetilde{a}} \|\widetilde{a}\|_1 \text{ such that } y_m = \Psi \widetilde{a}.$$

- ℓ^1 minimization is used instead of ℓ^0 minimization.
- Set $a_m = \widehat{a}_m^+$.
- Select ℓ significant frame elements, $\Psi_{k_1}, \ldots, \Psi_{k_\ell}$.
- The new coordinates for x_m are $(a_m[k_1], \ldots, a_m[k_\ell])$.

- Specifically constructed frames with built-in features have been utilized in remote sensing data processing (E. H. Bosch, A. Gonz'alez, J. Vivas, and G. Easley)
- 2D tight frames that provide a new way to analyze, visualize, and process data at multiple scales and directions was proposed by Bosch et al.
- Olshausen and his collaborators used learned dictionaries, which are frames, in their work on improving the performance of supervised classiffication algorithms for HSI data.
- Z. Xing, M. Zhou, A. Castrodad, G. Sapiro and L. Carin constructed dictionary learning algorithms for noisy and incomplete Hyperspectral images.

Feature Space Rotation for LE

Our final example deals with data recovery which exploits heterogeneous data structures. We begin with a brief description of the feature space rotations.

• Feature space rotation for LE is a modification from rotation for diffusion maps, introduced by Coifman and Hirn (2013).

R. R. Coifman and M. Hirn, Diffusion maps for changing data, Applied and Computational Harmonic Analysis, vol. 36 (2014) no. 1, pp. 79–107.

- For LE, define weight function as $a(x, y) = \frac{1}{2} \left(\delta_{x,y} \frac{k(x,y)}{\sqrt{m(x)m(y)}} \right)$, where $m(x) = \sum_{y} k(x, y)$.
- LE distance for two different kernels, k_{α} and k_{β} , is defined as

$$D(x_{\alpha}, y_{\beta}) = \|a_{\alpha}(x, \cdot) - a_{\beta}(y, \cdot)\|_{2}.$$

• Can show $D(x_{\alpha}, y_{\beta}) = \|\Phi_{\alpha}(x) - \mathcal{O}_{\beta \to \alpha} \Phi_{\beta}(y)\|_{\ell^2}$, where

$$(\mathcal{O}_{\beta \to \alpha} \mathbf{x})_i = \sum_j \mathbf{x}_j \langle \phi_{\alpha}^{(j)}, \phi_{\beta}^{(j)} \rangle_{L^2(\mathbf{X})}, \ \mathbf{x} \in \ell_{\beta}^2.$$

HSI and LIDAR Data: Gulfport

With A. Cloninger and T. Doster (2014) we proposed to use LE preimage for a data recovery application in heterogeneous setting.

Figure : Lidar and HSI data were acquired concurrently and coregistered using Optech Inc. Gemini Airborne Topographic LIDAR Mapper (ALTM) system, and ITRES Inc. hyperspectral Compact Airborne Spectrographic Imager (CASI-1500). Out of the original 72 HSI bands, 58 bands were selected for higher signal to noise ratio. Courtesy of Paul Gader, University of Florida, and Alina Zare, University of Missouri.

Figure : Euler Elastica Inpainting directly (left) and in the new representation (right)

J. Shen, S. H. Kang, and T. Chan, Euler's Elastica and Curvature-Based Inpainting, SIAM J. Appl. Math., 63 (2003) no. 2, pp. 564–592.

- Over these 3 days of lectures we have covered a wide range of methods in harmonic analysis that can be potentially applied in Big Data applications.
- Two major classes of techniques we have introduced were: multiscale methods and data-dependent kernel methods.
- There is also a long list of topics in harmonic analysis which can be applied in these applications, but which we have **not** had an opportunity to cover in this short tutorial.
- The major points which we emphasized are that harmonic analysis is one of the best approaches to deal with big data, but there is still a lot to be done before HA techniques are widely applicable in true big data settings.
